Procedural C	C++ OOP
1. Global data: Task arrays and status arrays are separate global variables, which can be accessed from different functions.	Encapsulation: Task data and related methods are organized inside classes, allowing controlled access.
2. Separate functions and data: The programmer must manually manage arrays and ensure functions work with the correct data.	Methods: Functions such as markDone(() belong to the Task object, making task operations easier to organize.
3.. Managing multiple tasks: Adding task-related operations requires separate arrays, functions, and index handling.	TaskList class: Stores multiple Task objects and provides addTask(), mmarkTaskDone(), and showTasks() methods in one organized structure.
